Our Goal Today!

Final Exams

Things in the Course

Things I studied

Things on the Exam

THIS WILL NOT HAPPEN!
Final Exam Logistics

- **Date**: Friday, June 6 – Sunday, June 8
- **Time**: Any 8 hour period from 8:00AM on Friday to 8:00PM on Sunday
- **Place**: Will be available electronically
- **Open book exam**: Allow the use of notes, lectures, recitations, homework
- **ABSOLUTELY NO COLLABORATION!** Violation of this will result in a failing grade for the course.
- Formula Sheet provided on Stellar
Outline

- **Topic 1**: Probability Theory
- **Topic 2**: Decision Analysis
- **Topic 3**: Discrete Random Variables
- **Topic 4**: Continuous Random Variables
- **Topic 5**: Covariance and Correlation
- **Topic 6**: Regression
- **Topic 7**: Linear Optimization
- **Topic 8**: Discrete Optimization
- **Topic 9**: Nonlinear Optimization
Random Variables

- Random variable: a function that assigns a numerical value to every possible outcome of an experiment

Example: Coin toss

If Heads: $X=1$  
If Tails: $X=0$
Probability Laws

- What rules does this function follow?
  1. The probability of each outcome must be non-negative \((p \geq 0)\)
     The largest possible probability is 1: this tells us that we are 100% certain that this outcome will occur.
  2. MOST IMPORTANTLY: the sum of the probabilities of all possible outcomes is always \(= 1\)
     - If all outcomes are: \(x_1, x_2, x_3, ..., x_n\)
     - Then the sum: \(P(X = x_1) + P(X = x_2) + ... + P(X = x_n) = p_1 + p_2 + ... + p_n = 1\)
  3. Mutually exclusive events: If you have a set of non-overlapping events, then the probability of this set is just the sum of the individual event probabilities.
Mean (Expected Value)

- Mean: the “weighted” average outcome
  - Formula:
  
  \[ E[X] = \mu_x = \sum_{i=1}^{n} x_i \cdot P(X = x_i) = \sum_{i=1}^{n} x_i p_i \]

- Average: the center of a set of numbers (all equally likely)
  - Formula:
  
  \[ A = \frac{1}{n} \sum_{i=1}^{n} x_i \]

- THEY ARE ONLY EQUAL IF ALL PROBABILITIES \( p_i \) ARE THE SAME!!
Decision Trees

Should I bring an umbrella today in case it rains?

Since $0.8 > -2$, I should bring an umbrella!!!

RVs: Discrete v. Continuous

Discrete

Examples
- # from rolling a die
- # of stock prices which will go up tomorrow

Values
- \( x_1, x_2, \ldots, x_n \)

Probabilities
- \( p_1, p_2, \ldots, p_n \)
- \( P(X = x_i) = p_i \)
- \( \sum p_i = 1 \)

Continuous

Distance die rolls
Amount stock prices go up tomorrow

Values
- range

Probabilities
- \( P(b \leq X \leq a) \), \( P(b \leq X) \), \( P(X \geq a) \), etc.

Graphic

Histogram: \( P(X = x_i) = p_i \)

Probability Density Function:
- \( P(b \leq X \leq a) = \text{area under curve between } a \text{ and } b \)
# RVs: Important Summary Statistics

<table>

RVs: Binomial Distribution (Discrete)

- There were three T/F questions on the Econ Exam, you have a 70% chance of getting each of them right, what is the probability you get all three correct? What is the mean number of questions you get right? The variance?

- Binomial!
  - $n$ independent trials, each with a success rate of $p$
  - $X \sim$ the total number of successes
  - $\mu=np, \quad \sigma^2=np*(1-p)$

- Remember: $P(X = x) = \frac{n!}{x!(n-x)!} * p^x (1 - p)^{n-x}$

- So $P(X = 3) = \frac{3!}{3!(3-3)!} * .7^3 (1 - .7)^{3-3} = .7^3 = .34$

- And $\mu=3*.7=2.1, \quad \sigma^2=3*.7*.3 = .62$
Computing probabilities with the Normal distribution:

You want: \( P(a \leq X \leq b) \) where \( X \) is \( N(\mu, \sigma) \)

1. Define: \[ Z = \frac{X - \mu}{\sigma} \] : \( Z \) is \( N(0,1) \)

\[
P(a \leq X \leq b) = P\left(\frac{a - \mu}{\sigma} \leq Z \leq \frac{b - \mu}{\sigma}\right)
\]

\[
= P\left(Z \leq \frac{b - \mu}{\sigma}\right) - P\left(Z \leq \frac{a - \mu}{\sigma}\right)
\]

2. Use the standard normal probability table (\( Z \) table)

2005 Exam: Problem 1 (d)

d) If X has mean 1, standard deviation 2 and Y has mean 1, standard deviation 4, then the standard deviation of Z=X+Y cannot exceed 6.

\[
\text{Var}(Z) = \text{Var}(X) + \text{Var}(Y) + 2\sigma_X \sigma_Y \text{CORR}(X,Y)
\]

Maximum value achieved when \(\text{CORR}(X,Y) = 1\)

\[
\text{Var}(Z) = 36, \ \sigma_Z = 6
\]
Sums of i.i.d RVs:
Central Limit Theorem

\[ X_1, X_2, \ldots, X_n \text{ independent identically distributed} \text{ random variables:} \]
\[ E[X_i] = \mu, \ Var(X_i) = \sigma^2 \]

- For \( n > 30 \), \( S_n = X_1 + X_2 + \ldots + X_n \) is approximately normal with mean \( n\mu \) and variance \( n\sigma^2 \) (standard deviation \( \sqrt{n}\sigma \))

\[ M_n = \frac{X_1 + X_2 + \ldots + X_n}{n} \]

- For \( n > 30 \), \( M_n \) is approximately normal with mean \( \mu \) and variance \( \sigma^2/n \) (standard deviation \( \sigma/\sqrt{n} \))

- The probability distribution of \( X_i \) does not matter;
- \( n \) does not have to be very large (30 is good enough);
- CLT requires only 2 pieces of information: the mean and SD of \( X_i \)
Silverware Example

- SilverwareInc has 3 products: Forks, Knives, and Spoons. They have kept track of sales, but only in aggregate form. They have found that the mean of yearly Silverware revenues is $3M, and the standard deviation of the yearly revenues is $1M. Revenues are Normally Distributed.

- What can you say about the distribution of the yearly revenues?
  - \( W = F+K+S \sim N(\mu=3, \sigma=1) \), in $M
Silverware Example

- SilverwareInc is selling world-class Forks, Knives, and Spoons. The mean and standard deviation of the number of daily sets sold are recorded in the table below, together with the price.

<table>
<thead>
<tr>
<th></th>

<td>8.5</td>
</tr>
<tr>
<td>Price ($)</td>
<td>10.0</td>
<td>10.0</td>
<td>11.0</td>
</tr>
</tbody>
</table>

- What can you say about the distribution of yearly sales of forks?
  - $F \sim N(\mu=365 \times 15.6, \sigma=8.3 \times \sqrt{365})$
Silverware Example

- What can you say about the distribution of yearly sales of forks?
  - F ~ N(µ=365*15.6, σ=8.3*√365)

- What is the probability that SilverwareInc’s revenues from forks is greater than 6,000 units this year?

\[ P(W \geq 6000) = P\left(\frac{W - \mu}{\sigma} \geq \frac{6000 - \mu}{\sigma}\right) \]

\[ = P\left(Z \geq \frac{6000 - 5694}{158.57}\right) = P(Z \geq 1.92) \]

\[ = 1 - P(Z \leq 1.92) \]
Outline

- **Topic 1**: Probability Theory
- **Topic 2**: Decision Analysis
- **Topic 3**: Discrete Random Variables
- **Topic 4**: Continuous Random Variables
- **Topic 5**: Covariance and Correlation
- **Topic 6**: Regression
- **Topic 7**: Linear Optimization
- **Topic 8**: Discrete Optimization
- **Topic 9**: Nonlinear Optimization
Linear Regression

• Predict a dependent variable $Y$ from a set of independent variables (predictors) $X_i$

• Assume $Y$ is a “straight-line” function of each of the $X_i$ variables, when all the others are fixed.
  • The slopes of each $X_i$’s relationship with $Y$ are coefficients $\beta_i$

• **Goal:** Pick coefficients to minimize errors (sum of squared residuals)
  $$\hat{y}_i = b_0 + b_1x_{1i} + \ldots + b_kx_{ki}$$

• The steps in which we accomplish this goal are as follows:
  • Calculate the model parameters that “best agree” with the available data ($\beta_k$).
  • Analyze the model and estimates and verify that they are reasonable.
  • Potentially revise initial model based on this analysis, and repeat.
• **Residuals** (errors), defined as: $e_i = y_i - \hat{y}_i$

• So we’re minimizing SSE: 

$$SSE = \sum_{i=1}^{n} e_i^2 = \sum_{i=1}^{n} (y_i - \hat{y}_i)^2$$

• $R^2$: Coefficient of determination

$R^2$ takes values between 0 and 1:

$$R^2 = 1 - \frac{\sum_{i=1}^{n} (y_i - \hat{y}_i)^2}{\sum_{i=1}^{n} (y_i - \bar{y})^2}$$

$R^2$: is the explained variation (by the model) divided by the total variation = the percent of variation that can be explained by the regression equation
Confidence Intervals

- A confidence interval tells us a range of values in which we expect an UNKNOWN parameter to lie (in our case, each of the $\beta_k$).

- This intervals depends on the data sample $(x_{k1}, x_{k2}, \ldots, x_{km})$!!! It depends on the mean and variance of this data set. If we had different data, we would get a different interval!

- A 95% confidence interval DOES NOT tell us that we have 95% likelihood of correctly estimating $\beta_k$.

- A 95% confidence interval DOES tell us that if we constructed this interval from 100 different data samples of size $m$, then 95 of these intervals would correctly contain the true (unknown) value of $\beta_k$. 
Regression model is good?

- $R^2$ closer to 1. (Although good value depends on situation.)
- Estimated coefficients make sense
  - Sign? Magnitude?
- Confidence Interval
  - If zero does not lie in the confidence interval: we are confident at the $\alpha\%$ level that $\beta_m$ is different from 0
  - If zero lies in the confidence interval: we should be skeptical that $Y$ depends linearly on $x_m$ and we might want to eliminate $x_m$ from the model.
Checklist for Evaluating a Linear Regression Model

- **Linearity:** Construct a scatter-plot for each explanatory variable check for linearity.

- **Signs of Regression Coefficients:** Check to see that the signs make intuitive sense.

- **Significance tests:** check if the regression coefficients are significantly different from zero (not included in the confidence interval).

- **R²:** Check if the value of R² is reasonably high.

- **Normality:** Check that the residuals are approximately Normally distributed by constructing a histogram of residuals.

- **Heteroscedasticity:** Do error terms have constant standard deviation? Plot the residuals with the observed values of each of the explanatory variables.

- **Multicollinearity:** Are two explanatory variables correlated?

Signs: if regression coeffs have “wrong” sign or we find high R² but one or more of the regression coeffs is not significantly different from 0. Check correlation table. Remove one of the variables from the model if there is high correlation.
An Ice Cream Example

The fat content in a gallon of chocolate ice cream is believed to depend on **Cream, Chocolate and Sugar** according to:

$$\text{Fat} = A + B \times \text{Cream} + C \times \text{Chocolate} + D \times \text{Sugar}$$

A multiple regression was run on data from 20 different batches of chocolate ice cream:

<table>
<thead>
<tr>
<th>Coefficients</th>
<th>Standard Error</th>
<th>Lower 95%</th>
<th>Upper 95%</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intercept</td>
<td>-8.94</td>
<td>19.95</td>
<td>-51.24</td>
</tr>
<tr>
<td>Cream (ounces)</td>
<td>0.93</td>
<td>0.12</td>
<td>0.67</td>
</tr>
<tr>
<td>Choc. (ounces)</td>
<td>2.07</td>
<td>0.60</td>
<td>0.80</td>
</tr>
<tr>
<td>Sugar (ounces)</td>
<td>2.47</td>
<td>1.33</td>
<td>-0.34</td>
</tr>
</tbody>
</table>
An Ice Cream Example

Correlation between different variables:

<table>
<thead>
<tr>
<th></th>
<th>Fat (gm)</th>
<th>Cream (ounces)</th>
<th>Choc. (ounces)</th>
<th>Sugar (ounces)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fat (gm)</td>
<td>1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Cream (ounces)</td>
<td>0.769</td>
<td>1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Choc. (ounces)</td>
<td>0.486</td>
<td>0.025</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>Sugar (ounces)</td>
<td>0.280</td>
<td>-0.099</td>
<td>0.409</td>
<td>1</td>
</tr>
</tbody>
</table>

- **Check the 95% CI for Choc. coefficient**

- **Critique model**
The coefficients for Cream, Choc and Sugar appear to make sense.

**Significance test:**

0 is in the confidence interval for Sugar coeff. so Sugar should be excluded from the regression.
\( R^2 \): The value for \( R^2 \) is 0.8433 which indicates that the model has a high level of prediction.

**Multicollinearity:**

<table>
<thead>
<tr>
<th></th>
<th>Fat (gm)</th>
<th>Cream (ounces)</th>
<th>Choc. (ounces)</th>
<th>Sugar (ounces)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fat (gm)</td>
<td>1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Cream (ounces)</td>
<td>0.769</td>
<td>1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Choc. (ounces)</td>
<td>0.486</td>
<td>0.025</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>Sugar (ounces)</td>
<td>0.280</td>
<td>-0.099</td>
<td>0.409</td>
<td>1</td>
</tr>
</tbody>
</table>

There is a high correlation between chocolate and sugar (>0.4) hence we should eliminate one of these variables - sugar because it is less correlated with fat.
There appears to be no heteroscedasticity

Heteroscedasticity:

\[ \text{Residuals} \]

\[ \text{Cream (ounces)} \]

\[ \text{Chocolate Residual Plot} \]

\[ \text{Cream Residual Plot} \]

\[ \text{Chocolate (ounces)} \]
An Ice Cream Example

Residual Distribution:

The residuals appear to be normally distributed
Outline

- **Topic 1**: Probability Theory
- **Topic 2**: Decision Analysis
- **Topic 3**: Discrete Random Variables
- **Topic 4**: Continuous Random Variables
- **Topic 5**: Covariance and Correlation
- **Topic 6**: Regression
- **Topic 7**: *Linear Optimization*
- **Topic 8**: Discrete Optimization
- **Topic 9**: Nonlinear Optimization
Optimization terminology

**Decision Variable:** Describes a decision that needs to be made, e.g. how many items to produce.

**Objective Function:** An expression (in terms of the variables) that needs to be minimized or maximized.

**Constraint:** An expression that restricts the values of the variables.
Steps in formulation

1. Define the decision variables.

2. Write the objective as a function of these vars. Determine whether max or min.

3. Write the constraints as functions of these vars. Either $\leq, \geq, =$.

4. Determine the variable restrictions, e.g. non-negative, integer. Be careful of units!
About Shadow Prices

- Associated with each constraint.
- Shadow price = 0 for non-binding constraints.
- The shadow price is the change in the objective value per unit change in the right hand side, given all other data remain the same.
- Allowable range (decrease/increase)
  - If r.h.s changes within range: Shadow price tells us rate of change in the optimal objective function value; we know exactly the new objective value without re-solving the problem.
  - If r.h.s changes outside range: We cannot determine the rate of change in the optimal objective value anymore; we need to solve the optimization pb again!
Avoid frequent mistakes!

• Forgetting the **non-negativity** restrictions

• Confusing **Maximizing** with **Minimizing**

• **Inconsistent** and/or **incorrect** units

• Reversing the **signs** of the constraints

• Wrong interpretation of the **shadow prices**.

• Change in R.H.S **outside** the allowable range
Sloan Alloy Corp. manufactures four different types of alloys for aircraft construction, denoted A, B, C and D, from three basic metals: aluminum, copper and magnesium. The profit margins for each of the alloys are $105, $45, $95, and $140 per ton, for alloys A, B, C, and D, respectively. The proportion of metals in the alloys is shown in the following table.

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aluminum</td>
<td>0.3</td>
<td>0.4</td>
<td>0.1</td>
<td>0.15</td>
</tr>
<tr>
<td>Copper</td>
<td>0.3</td>
<td>0.1</td>
<td>0.25</td>
<td>0.4</td>
</tr>
<tr>
<td>Magnesium</td>
<td>0.4</td>
<td>0.5</td>
<td>0.65</td>
<td>0.45</td>
</tr>
</tbody>
</table>

For example, one ton of alloy A consists of 0.3 tons of aluminum, 0.3 tons of copper and 0.4 tons of magnesium. The monthly maximum supplies of aluminum, copper and magnesium are 600, 400 and 800 tons per month, respectively.
Each type of alloy requires a different number of machine hours for production. Alloys A, B, C, and D require 4, 5, 3, and 6 hours/ton, respectively.

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>Machine hours per ton</td>
<td>4</td>
<td>5</td>
<td>3</td>
<td>6</td>
</tr>
</tbody>
</table>

The total number of machine hours available per month is 8,000 hours. The company can sell all alloy that it produces. The company would like to determine how many tons of each alloy to produce to maximize the profits per month.
2007 Exam – Problem 3

A linear optimization model formulation and solution to this problem is as follows:

MAX: \( 105A + 45B + 95C + 140D \)

SUBJECT TO:

Aluminum Supply \( 0.3A + 0.4B + 0.1C + 0.15D \leq 600 \)
Copper Supply \( 0.3A + 0.1B + 0.25C + 0.4D \leq 400 \)
Magnesium Supply \( 0.4A + 0.5B + 0.65C + 0.45D \leq 800 \)
Machine hours \( 4A + 5B + 3C + 6D \leq 8000 \)
Nonnegativity \( A, B, C, D \geq 0 \)
(a) (4 points) What is the optimal solution? What is the optimal profit per month?

Optimal solution: 0 tons of A, 632.4 of B, 284.6 of C and 664 of D.
Optimal profit: \( 105 \times 0 + 45 \times 632.4 + 95 \times 284.6 + 140 \times 664 = $148,455/mth \)
2007 Exam – Problem 3 (b)

</tbody>
</table>

(b) (2 points) Which are the binding constraints?

Binding constraints: Supply of copper and magnesium and the available machine time.
(c) (2 points) Why is the allowable increase to the Aluminum supply constraint right-hand side equal to 1E+30 in the sensitivity report?

Not a binding constraint. Optimal solution is already not utilizing all available aluminum. An increase of any amount of aluminum does not report us any value or extra profits.
(d) (3 points) Assuming all other data are unchanged, what would the new optimal profit be, if we realize we have to perform preventive maintenance to the machines, which will decrease the available machine hours per month by 200 hours?

Our profits will decrease by $0.5 \times 200 = $100 / month.
(e) (3 points) Assuming all other data are unchanged, if we could increase our supply of one of the metals by 100 tons per month, which one should we choose? What would be the resulting increase in optimized profit?

Increase supply of copper by 100 tons: highest shadow price and 100 tons is within its allowed increase.
The profits would increase by \(318.6 \times 100 = \$31,860 / \text{month}\).
(f) (3 points) Imagine you find out that to produce alloy A you need 5 hours of machine hours per ton (instead of 4). How would the profits per month change? Would your answer be different if you found out that you needed 1 machine hour per month (instead of 4)?

Would not change the result: additional restrictive constraint on the production of alloy A, don’t produce any.

If we only needed 1 machine hour, maybe worth producing A. Cannot tell.
(g) (3 points) How would the optimal profit change, if we increase the maximum Copper supply per month by 200 tons? Be as specific as possible.

Maximum allowable increase is 156.9.
Profit would be at least 156.9 * 318.6 = $49,998 higher per month.
Profits cannot be higher than 200 * 318.6 = $63,720 / month.
Outline

- **Topic 1**: Probability Theory

- ** Topic 3**: Discrete Random Variables
- ** Topic 4**: Continuous Random Variables
- ** Topic 5**: Covariance and Correlation
- ** Topic 6**: Regression
- ** Topic 7**: Linear Optimization
- ** Topic 8**: Discrete Optimization
- ** Topic 9**: Nonlinear Optimization
Discrete Optimization

- Feasible region is discrete
  - integer (# of people to hire, # of planes to build)
  - binary (sell division i? use factory i to serve customers?)
    
    \[ x_i = 1 \text{, if decision } i \text{ taken (0 otherwise)} \]

- Not as “easy” to solve as Linear Optimization

- Many problems are discrete, but a linear approximation is sufficient (e.g. pottery manufacturing)

- No shadow price / sensitivity analysis!!

- Can be used to model complicated costs / constraints
An electrical utility company each day is deciding which generators to start up.

It has three generators (see below).

There are two periods in a day, and the number of megawatts needed in the first period is 2900. The second period requires 3900 megawatts. Unused electricity left over from period 1 can be used in period 2.

It wants to minimize total cost.

Formulate and solve this problem!

<table>
<thead>
<tr>
<th>Generator</th>

</table>
Formulation

- Define Decision Variables
  - $X_{A1}$ = machine A to be used in period 1
  - $X_{A2}$ = machine A to be used in period 2
  - $X_{B1}$ = machine B to be used in period 1
  - $X_{B2}$ = machine B to be used in period 2
  - $X_{C1}$ = machine C to be used in period 1
  - $X_{C2}$ = machine C to be used in period 2
  - $Y_{A1}$ = amount of electricity produced by machine A in period 1
  - $Y_{A2}$ = amount of electricity produced by machine A in period 2
  - $Y_{B1}$ = amount of electricity produced by machine B in period 1
  - $Y_{B2}$ = amount of electricity produced by machine B in period 2
  - $Y_{C1}$ = amount of electricity produced by machine C in period 1
  - $Y_{C2}$ = amount of electricity produced by machine C in period 2
Objective Function & Constraints

- **Objective Function**
  \[
  \text{minimize } 3000 (X_{A1} + X_{A2}) + 2000 (X_{B1} + X_{B2}) + 1000 (X_{C1} + X_{C2}) + \\
  +5 (Y_{A1} + Y_{A2}) + 4 (Y_{B1} + Y_{B2}) + 7 (Y_{C1} + Y_{C2})
  \]

- **Subject to:**
  - **Capacity:**
    - Machine A: \(Y_{A1} \leq 2100 X_{A1} ; Y_{A2} \leq 2100 X_{A2}\)
    - Machine B: \(Y_{B1} \leq 1800 X_{B1} ; Y_{B2} \leq 1800 X_{B2}\)
    - Machine C: \(Y_{C1} \leq 3000 X_{C1} ; Y_{C2} \leq 3000 X_{B2}\)
  - **Demand:**
    - Period 1: \(Y_{A1} + Y_{B1} + Y_{C1} \geq 2900\)
    - Period 2: \(Y_{A2} + Y_{B2} + Y_{C2} + Y_{A1} + Y_{B1} + Y_{C1} - 2900 \geq 3900\)
  - **Binary:** \(X_{A1}, X_{A2}, X_{B1}, X_{B2}, X_{C1}, X_{C2} = \{1 \text{ if used; } 0 \text{ otherwise}\}\)
  - **Non-negativity:**
    - \(Y_{A1}, Y_{A2}, Y_{B1}, Y_{B2}, Y_{C1}, Y_{C2} \geq 0\)

**Other constraints:**

- Xij binary
- Xij, Yij >= 0
• Recall our Decision Variables
  • $X_{mi} =$ machine m to be used in period i, $m \in \{A, B, C\}$, $i \in \{1,2\}$
  • $Y_{mi} =$ amount of electricity produced by machine m in period i

• For each of the following statements / conditions, write down the corresponding linear constraint(s) that should be added to the model

1. If we use machine A in period 1, then we must also use it in period 2
   • $X_{A2} \geq X_{A1}$

2. If we use machine A in period 1, then we must also use it in period 2, and vice-versa
   • $X_{A2} \geq X_{A1}$; $X_{A1} \geq X_{A2}$
   • Or, more compactly, $X_{A2} = X_{A1}$

3. Machine B should never be used in both periods
   • $X_{B1} + X_{B2} \leq 1$
   • This could be phrased in other ways (e.g. “if machine B is used in period 1, it should not be used in period 2”)

4. Machine C should be used in exactly one period
   • $X_{C1} + X_{C2} = 1$
More Logical Constraints

• Recall our Decision Variables
  • $X_{mi} =$ machine m to be used in period i, $m \in \{A, B, C\}, \ i \in \{1,2\}$
  • $Y_{mi} =$ amount of electricity produced by machine m in period i

• For each of the following statements / conditions, write down the corresponding linear constraint(s) that should be added to the model

5. Machines A and B must always be used together
  • $X_{A1} = X_{B1} \ ; \ X_{A2} = X_{B2}$

6. If we use either A or B in period 1, then we must use C in period 2
  • $X_{A1} \leq X_{C2} \ ; \ X_{B1} \leq X_{C2}$
  • How about $X_{A1} + X_{B1} \leq 2X_{C2}$?

7. We must use at least 2 machines in period 1
  • $X_{A1} + X_{B1} + X_{C1} \geq 2$

8. We must use at most two machines in period 2
  • $X_{A2} + X_{B2} + X_{C2} \leq 2$

9. (Trickier) Recall that the maximum capacity for A is 2100. Using words, explain what the following constraint might be able to achieve:
  • $X_{A2} \leq 1 - (Y_{A1} - 0.95 \times 2100) / (0.05 \times 2100)$

Steps in a Formulation

0. Same steps as LP, but objective and constraints can be non-linear (e.g. Minimize $x^2+y^2; x*y+y\leq 5$)

1. Define the decision variables.

2. Write the objective as a function of these vars. Determine whether max or min.

3. Write the constraints as functions of these vars. Either $\leq, \geq, =$.

4. Determine the variable restrictions, e.g. non-negative, integer. Be careful of units!

All Lagrange Multipliers are zero!
All constraints are non-binding around the close proximity of the optimal solution.
Optimal solution occurs in the interior of the feasible region.
Problem 5. (20 points) Exeter Investments (EI) has decided to construct a new portfolio which will be comprised of IT (information technology) and energy companies' stocks. For this reason, EI collected the expected return, standard deviations and return correlations data for companies A, B, C, D, E, and F, which belong to those sectors. This data is displayed in Tables 1 and 2.

2007 Exam Problem 5

a) **(5 points)** EI would like the portfolio to have a maximum risk of 15%. Write down a nonlinear optimization problem to determine the weights that yield the maximum possible expected return satisfying this target risk requirement.

Decision Variables: $w_i$—what percentage of the portfolio do I invest in stock $i$ for $i=A,B,...,F$

$$\text{max} \quad 14w_A + 17w_B + 12w_C + 4w_D + 19w_E + 25w_F$$  
(Portfolio return)

$$\sqrt{19^2 w_A^2 + 28^2 w_B^2 + 17^2 w_C^2 + 7^2 w_D^2 + 35^2 w_E^2 + 45^2 w_F^2} \leq 15$$  
(Risk maximum)

$$\begin{align*} 
+2w_A \cdot w_B \cdot 0.7 \cdot 19 \cdot 28 - 2w_B \cdot w_C \cdot 0.4 \cdot 28 \cdot 17 + 2w_A \cdot w_C \cdot 0.2 \cdot 19 \cdot 17 \\
w_A + w_B + w_C + w_D + w_E + w_F = 1 \\
w_A, w_B, w_C, w_D, w_E, w_F \geq 0 
\end{align*}$$  
(Invest whole portfolio)  
(Non-negative weights)

b) **(3 points)** In looking at the sensitivity report with respect to the optimization problem in a), the shadow price associated with the constraint on a maximum risk of 15% was found to be $\boxed{0.0143}$, but the sign in front of it cannot be read. That is, this shadow price is either 0.0143 or -0.0143. Which one of these possible values is correct?

+: Raising the risk maximum makes the feasible region bigger (we are less restricted). Since we are maximizing, this means we may find a new optimum with a higher return. Thus the shadow price is $\geq 0$. 

2007 Exam Problem 5

(c) (4 points) Additionally EI wants to ensure that the risk corresponding to the part of the portfolio consisting of EI companies does not exceed 17%. Incorporate this requirement into your formulation.

A, B, D, F are IT companies. We add the constraint:

$$\sqrt{19^2 w_A^2 + 28^2 w_B^2 + 7^2 w_D^2 + 45^2 w_F^2 + 2 w_A \cdot w_B \cdot 0.7 \cdot 19 \cdot 28} \leq 17$$

(d) (5 points) As of December 10 close, the market capitalization of energy stocks represented 12.08% of the overall S&P 500 market capitalization. EI would like to make sure that in their portfolio, the relative value of energy stocks is within +/- 2% of this S&P 500 benchmark. Show how EI can incorporate this requirement into their formulation.

C and E are Energy companies. We add the constraints:

$$0.1008 \leq w_C + w_E \leq 0.1408$$
